

1. One common Git mistake is committing files that should not be saved, like large files, passwords, or private information. If the file is deleted later, it can still stay in Git history. That is why it is important to check files before committing and use `.gitignore` for files that should not be tracked.

2. When I used `git stash`, Git saved my changes and made my working folder clean again. When I ran `git log --all --oneline`, I could see the commit history in a shorter format. After using `git stash pop`, my saved changes came back. This is useful when I need to switch tasks or branches without losing my work.
